Percutaneous Penetration of [ $^{14}\text{C}$ ]Formaldehyde ( $\text{H}^{14}\text{CHO}$ ) in Rhesus Monkeys, and Disposition of  $\text{H}^{14}\text{CHO}$  after IV Dose in Monkeys and Fischer 344 Rats. A. R. Jeffcoat\*, H. B. Marr\*, B.M. Sadler\*, D. Feldman\*, R. Bogoroch\*† (SPON: C. E. Cook) Research Triangle Institute, Res. Tri. Park, N.C. 27709 and Formaldehyde Institute (FI)†, Scarsdale, NY 10583.

Penetration of  $\text{CH}_2\text{O}$  through skin was studied because of its wide-spread environmental presence. In 5 male monkeys 24 hr after dermal application of  $0.4\text{--}0.9 \mu\text{g}/\text{cm}^2$  of  $\text{H}^{14}\text{CHO}$ , most had evaporated (52%) or was bound (33%) to the surface layers of skin at the application site. Percutaneous penetration of  $^{14}\text{C}$  was very low. Based on 24 hr excretion of  $^{14}\text{C}$  in breath following separate dermal and IV administration of  $\text{H}^{14}\text{CHO}$ , percutaneous penetration was 0.27% of dose; 0.46% of dose based on urinary excretion. Tissues and organs of a monkey necropsied 24 hr after dermal dosing contained  $<0.2\%$  of dose. Breath was the primary route of excretion of  $^{14}\text{C}$  following IV doses of  $\text{H}^{14}\text{CHO}$  to 4 monkeys (47% of dose excreted in 4 hr, 51% in 1 day, 55% in 5 days). Urinary excretion was 2.4% of dose in day 1, 4.2% in 10 days. After an IV dose of  $\text{H}^{14}\text{CHO}$  to rats, ca. 70% of dose was excreted in breath as  $^{14}\text{CO}_2$ , 9% in urine and 2% in feces in 10 days. Remainder of dose was quantitatively recovered from the carcasses. Sex or dose level did not effect amount or rate of excretion. [Supported by contract with American Textile Manufacturers Inst. and FI].
